More fiches *here*

General

- The distributed system is made of a finite set of **processes**: each process models a **sequencial** program
- Every pair of processes is connected by a link through which the processes exchange messages
- Safety is a property which states that nothing bad should happen
- Liveness is a property which states that something good should happen
- Twos kinds of failures are mainly considered
 - Omissions: The process omits to send messages it is supposed to send
 - Arbitrary: The process sends messages it is not supposed to send
- A **correct** process is a process that does not fail (that does not crash)
- A **Failure detector** is a distributed oracle that provides processes with suspicions about crashed processes
 - It is implemented using timing assumptions
 - Perfect :
 - * Strong Completness: Eventually, every process that crashes is permanantly suspected by every other correct process
 - * String Accuracy: No process is suspected before it crashes
 - Eventually Perfect:
 - * Strong Completness
 - * Eventually Strong Accuracy: Eventually, no correct process is ever suspected

Fair-loss Links

- **FL1. Fai-loss**: If a message is sent infinitely often by p_i to p_j n and neither p_i or p_j crashes then m is delivered infinitely often by p_j
- **FL2. Finite duplication**: If a message m is sent a finite number if times by p_i to p_j , m is delivered a finite number of times by p_i
- FL3. No creation: No message is delivered unless it was sent

Stubborn Links

- SL1. Stubborn delivery: If a process p_i sends a message m to a correct process p_j , and p_i does not crash, then p_j delivers m an infinite number of times
- SL2. No creation: No message is delivered unless it was sent

```
Implements: StubbornLinks (sp2p)
Uses : FairLossLinks (flp2p)
upon event <sp2pSend, dest, m> do
    while (true) do
    trigger <flp2pSend, dest, m>
upon event <flp2pDeliver, src, m> do
    trigger <sp2pDeliver, src, m>
```

Reliable (Perfect) Links

- PL1. Validity: If p_i and p_j are correct
- PL2. No duplication: No message is delivered (to a process) more than once
- PL3. No creation: No message is delivered unless it was sent
- Roughly speaking, reliable links ensure that messages exchanged between correct processes are not lost

```
Implements: PerfectLinks (pp2p)
Uses: StubbornLinks (sp2p)
upon event <Init> do delivered := emptySet
upon event <pp2pSend, dest, m> do
    trigger <sp2Send, dest, m>
```

```
upon event <sp2pDeliver, src, m> do
  if m not in delivered then
    trigger <pp2pDeliver, src, m>
    add m to delivered
```

Reliable Broadcast

Best-effort Broadcast (beb)

- **BEB1.** Validity: If p_i and p_j are correct then every message broadcast by p_i is eventually delivered by p_y
- BEB2. No duplication : No message is delivered more than once
- BEB3. No creation: No messages is delivered unless it was broadcast

```
Implements: BestEffortBroadcast (beb)
Uses: PerfectLinks (pp2p)
upon event <br/>bebBroadcast, m> do
   forall pi in S do
     trigger <pp2pSend, pi, m>
upon event <pp2pDeliver, pi, m> do
   trigger <dedDeliver, pi, m>
```

Reliable Broadcast (rb)

- RB1 = BEB1
- RB2 = BEB2
- RB3 = RB3
- RB4. Agreement: For any message m, if any correct process delivers m, then every correct process delivers m

```
Implements: ReliableBroadcast (rb)
Uses:
  BestEffortBroadcast (beb)
  PerfectFailureDetector (P)
upon event <Init> do
  delivered := emptySet
  correct := S
  forall pi in S do from[pi] := emptySet
upon event <rbBroadcast, m> do
  delivered := delivered U {m}
  trigger <rbDeliver, self, m>
  trigger <bebBroadcast, [data, self, m]>
upon event <crash, pi> do
  correct := correct \{pi}
  forall [pj, m] in from[pi] do
    trigger <bebBroadcast, [data, pj, m]>
upon event <bebDeliver, pi, [data, pj, m] > do
  if m not in delivered then
    delivered := delivered U {m}
    trigger <rbDeliver, pj, m>
    if pi not in correct then
      trigger <bebBroadcast, [data, pj, m]>
    else
      from[pi] := from[pi] U {[pj, m]}
```

Uniform Reliable Broadcast (urb)

- URB1 = BEB1
- URB2 = BEB2
- URB3 = BEB3
- URB4. Uniform Agreement: For any message m, if any process delivers m, then every process delivers m

```
Implements: UniformBroadcast (urb)
  BestEffortBroadcast (beb)
  PerfectFailureDetector (P)
upon event <Init> do
  correct := S
  delivered := forward := emptySet
  ack[Message] := emptySet
upon event <urbBroadcast, m> do
  forward := forward U {[self, m]}
  trigger <bebBroadcast, [data, self, m]>
upon event <bebDeliver, pi, [data, pj, m]> do
  ack[m] := ack[m] U \{pi\}
  if [pi, m] not in forward then
    forward := forward U {[pj, m]}
    trigger <bebBroadcast, [data, pj, m]>
upon event (for any [pj, m] in forward) <correct in ack[m] > and <m not in delivered > do
  delivered := delivered U {m}
  trigger <urbDeliver, pj, m>
```

Causal Broadcast

- A non-blocking algorithm using the past
- A blocking algorithm using vector clocks

Causality

- Let m_1 and m_2 be any two messages: $m_1 \to m_2$ (m_1 causally precedes m_2) iff
 - C1. Fifo order: Some process p_i broadcast m_1 before broadcasting m_2
 - C2. Local order: Some process p_i delivers m_1 and then broadcast m_2
 - C3. Transitivity: There is a message m_3 such that $m_1 \to m_3$ and $m_3 \to m_2$

Causal Broadcast

• CO: If any process p_i delivers a message m_2 , then p_i must have delivered every message m_1 such that $m_1 \to m_2$

Reliable Causal Broadcast (rcb)

- RB1, RB2, RB3, RB4
- CO

Uniform Causal Broadcast (ucb)

- URB1, URB2, URB3, URB4
- CO

Reliable Causal Order Broadcast (rco)

```
Implements: ReliableCausalOrderBroadcast (rco)
Uses : ReliableBroadcast (rb)
upon event <Init> do
  delivered := past := emptySet
upon event <rcoBroadcast, m> do
  trigger <rbBroadcast, [data, past, m]>
 past := past U {[self, m]}
upon event <rbDeliver, pi [data, pastm, m]> do
  if m not in delivered then
    forall [sn, n] in pastm do
      if n not in delivered then
        trigger <rcoDeliver, sn, n>
        delivered := delivered U {n}
        past := past U {[self, n]}
    trigger <rcoDeliver, pi, m>
    delivered := delivered U {m}
    past := past U {[pi, m]}
```

```
Implements ReliableCausalOrderBroadcast (rco)
Uses: ReliableBroadcast (rb)
upon event <Init> do
  forall pi in S: VC[pi] := 0
  pending := emptySet
upon event <rcoBroadcast, m> do
  trigger <rcoDeliver, self, m>
  trigger <rbBroadcast, [data, VC, m]>
  VC[self] := VC[self] + 1
upon event <rbDeliver, pj, [data, VCm, m]> do
  if pj not self then
    pending := pending U (pj, [data, VCm, m])
    deliver-pending
procedure deliver-pending is
  while (s, [data, VCm, m]) in pending do
    if forall pk: (VC[pk] >= VCm[pk]) do
      pending := pending - (s, [data, VCm, m])
      trigger <rcoDeliver, self, m>
      VC[s] := VC[s] + 1
```

- These algo ensure causal reliable broadcast
- If we replace reliabe broadcast with uniform reliabe broadcast, these algo would ensure uniform causal broadcast

Total Order Broadcast (tob)

- In reliable broadcast, the processes are free to deliver messages in any order they wish
- In causal broadcast, the processes need to deliver messages according to some order (causal order)
 - The order imposed by causal broadcast is however partial: some messages might be delivered in different order by the processes
- In **total order** broadcast, the processes must deliver all messages according to the same order (i.e. the order is now total)
 - This order does not need to respect causality (or event FIFO ordering)
- RB1. Validity: If p_i and p_j are correct, then every message broadcast by p_i is eventually delivered by

 p_j

- RB2. No duplication: No message is delivered more than once
- RB3. No creation : No message os delivered unless it was broadcast
- RB4. (Uniform) Agreement: For any message m. If a correct (any) process delivers m, then every correct process delivers m
- (Uniform) Total order: Let m and m' be any two messages. Let p_i be any any (correct) process that delivers m without having delivered m'. Then no (correct) process delivers m' before m

(Uniform) Consensus

- In the (uniform) consensus problem the processes propose values and need to agree on one among these values
- C1. Validity: Any value decided is a value proposed
- C2. (Uniform) Agreement: No two correct (any) processes decide differently
- C3. Termination: Every correct process eventually decides
- C4. Integrity: Every process decides at most once

Total Order (to)

```
Implements: TotalOrder (to)
Uses:
  ReliableBroadcast (rb)
  Consensus (cons)
upon event <Init> do
  unordered := delivered := emptySet
  wait := false;
  sn := 1
upon event <toBroadcast, m> do
  trigger <rbBroadcast, m>
upon event <rbDeliver, sm, m> and (m not in delivered) do
  unordered := unordered U {(sm, m)}
upon event (unordered not emptySet) and not wait do
  wait := true
  trigger <Propose, unordered>sn
upon event <Decide, decided>sn do
  unordered := unordered \ decided
  ordered := deterministicSort(decided)
  forall (sm, m) in ordered do
   trigger <toDeliver, sm, m>
   delivered := delivered U {m}
  sn := sn + 1
  wait = false
```

Shared Memory

Regular Register

- Assumes only one writer
- Provides strong guarantees when there is no concurrent operations
- When some operations are concurrent, the register provides minimal guarantees
- Read() returns:
 - The last value written if there is no concurrent or failed operations

- Otherwise the last value written on *any* value concurrently written i.e. the input parameter of some Write()
- We assume fail-stop model
 - Process can fail by crashing (no recovery)
 - Channels are reliable
 - Failure detection is perfect
- $\bullet~$ We implement a ${\bf regular}$ register
 - Every process p_i has a local copy of the register value v_i
 - Every process reads locally
 - The writer writes **globally**

```
Write(v) at pi
  send [W, w] to all
  forall pj, wait until either
   receive [ack] or
   detect [pj]
  return ok
```

```
Read() at pi
return vi
```

```
At pi
when receive [W, w] from pj
vi := v
send [ack] to pj
```

- We assume while failure detection is not perfect
 - $-P_1$ is the writer and any process can be reader
 - A mojority of the process is correct
 - Channels are reliable
- We implement a **regular** register
 - Every process p_i maintains a local copy of the register v_i , as well as a sequence number sn_i and a read timestamp rs_i
 - Process p_1 maintains in addition a timestamp ts_1

```
Write(v) at p1
  ts1 ++
  send [W, ts1, v] to all
  when receive [W, ts1, ack] from majority
    return ok
```

```
Read() at pi
  rsi ++
  send [R, rsi] to all
  when receive [R, rsi, snj, vj] from majority
  v := vj with the largest snj
  return v
```

```
At pi
  when receive [W, ts1, v] from p1
  if ts1 > sni then
    vi = v
    sni := ts1
    send[W, ts1, ack] to p1
  when receive [R, rsj] from pj
  send [R, rsj, sni, vi] to pj
```

Atomic Register

- An **Atomic Register** provides strong guarantees event when there is concurrency and failures: the execution is equivalent to a sequencial and failure-free execution
- Every failed (write) operation appears to be either complete or not to have been invoked at all
- Every complete operation appears to be executed at some instant between its invocation and reply time events
- We implement a fail-stop 1-N atomic register
 - Every process maintais a local value of the register as well as a sequence number
 - The writer, p_1 , maintains, in addition a timestamp ts_1
 - Any process can read in the register

```
Write(v) at p1
  ts1++
  send [W, ts1, v] to all
  forall pi wait until either
    receive [ack] or
    detect [pi]
 return ok
Read() at pi
  send [W, sni, vi] to all
  forall pi wait until either
    receive [ack] or
    suspect [pj]
 return vi
  When pi receive [W, ts, v] from pj
    if ts > sni then
     vi := v
      sni := ts
    send [ack] to pj
```

• We implement a fail-stop N-N atomic register

```
Write(v) at pi
  send [W] to all
  forall pj wait until either
    receive [W, snj] or
    suspect [pj]
  (sn, id) := (highest snj + 1, i)
  send [W, (sni, id), v] to all
  forall pj wait until either
    receive [W, (sn, id), ack] or
    detect [pj]
  return ok
```

```
Read() at pi
  send [R] to all
  forall pj wait until either
   recieve [R, (snj, idj), vj] or
   suspect pj
  v = vj with the highest (snj, idj)
  (sn, id) = highest (snj, idj)
```

```
send [W, (sn, id), v] to all
  forall pj wait until either
    receive [W, (sn, id), ack] or
    detect [pj]
  return v
At pi
T1:
  when receive [W] from pj
    send [W, sn] to pj
  when receive [R] from pj
    send [R, (sn, id), vi] to pj
T2:
  when receive [W, (snj, idj), v] from pj
    if (snj, idj) > (sn, id) then
      vi := v
      (sn, id) = (snj, idj)
    send [W, (sn, id), ack] to pj
  when receive [W, (snj, idj), v] from pj
    if (snj, idj) > (sn, id) then
      vi := v
      (sn, id) := (snj, idj)
    send [W, (sn, id), ack] to pj
```

- From fail-stop to fail-silent
 - We assume a mojority of correct processes
 - In the 1-N algorithm, the writer writes in a majority using a timestamp determined locally and the reader selects a value from a majority and then imposes this value on a majority
 - In the N-N algorithm, the writers determines first the timestamp using a majority

Terminating Reliable Broadcast (TRB)

- Like reliable broadcast, terminating reliable broadcast (TRB) is a communication primitive used to disseminate a message among a set of processes in a reliable way
- TRB is however strictly stronger than (uniform) reliable broadcast
- Like with reliable broadcast, correct processes in TRB agree on the set of messages they deliver
- Like with (uniform) reliable broadcast, every correct process in TRB delivers every message delivered by any correct process
- Unlike with reliable broadcast, every correct process delivers a message, event if the broadcaster crashes
- The problem is defined for a specific broadcaster process $p_i = src$ (know by all processes)
 - Process src is supposed to broadcast a message m (distinct from φ)
 - The other processes need to deliver m if src is correct but may deliver φ is src crashes
- TRB1. Integrity: If a process delivers a message m, then either m is φ or m was broadcasted by src
- TRB2. Validity: If the sender src is correct and broadcasts a message m, then src eventually delivers m
- TRB3. (Uniform) Agreement: For any message m, if a correct (any) process delivers m, then every correct process delivers m
- TRB4. Termination: Every correct process eventually delivers exactly one message

```
Implements: trbBroadcast (trb)
Uses:
    BestEffortBroadcast (beb)
    PerfectFailureDetector (P)
```

```
Consensus (cons)
upon event <Init> do
prop := 0
correct := S
upon event <trbBroadcast, m> do
    trigger <bebBroadcast, m>
upon event <crash, src> and (prop = 0) do
    prop := phi
upon event <bebDeliver, src, m> and (prop = 0) do
prop := m
upon event (prop not 0) do
    trigger <Propose, prop>
upon event <Decide, decision> do
    trigger <trbDeliver, src, decision>
```

- We give an algorithm that implements P unsign TRB. More precisely, we assume that every process p_i can use an infinite number of instances of TRB where p_i is the sender src
 - 1. Every process p_i keeps on trbBroadcasting messages m_{i1}, m_{i2} etc
 - 2. If a process p_k delivers φ_i , p_k suspects p_i

Non-Blocking Atomic Commit (NBAC)

- A transaction is an atomic program describing a sequence of accesses to shared and distributed information
 - Can be determined either by **committing** or **aborting**
- Atomicity: a transaction either performs entirely or none at all
- Consistency: a transaction transforms a consistent state into another consistent state
- Isolation : a transaction appears to be executed in isolation
- Durability: the effects of a transaction that commits are permanent
- As in consensus, every process has an initial value 0 (no) or 1 (yes) and must decide on a final value 0 (abort) or 1 (commit)
- The proposition means the ability to commit the transaction
- The decision reflects the contract with the user
- Unlike consensus, the processes here seek to decide 1 but every process has a veto right
- NBAC1. Agreement: No two processes decide differently
- NC1C2. Termination: Every correct process eventually decides
- NBAC3. Commit-Validity: 1 can only be decided if all process propose 1
- NBAC4. Abort-Validity: 0 can only be decided if some process crashes of votes 0

```
Implements: nonBlockingAtomicCommit (nbac)
Uses:
    BestEffortBroadcast (beb)
    PerfectFailureDetector (P)
    UniformConsensus (uniCons)
upon event <Init> do
    prop := 1
    delivered := emptySet
    correct := pi
upon evnet <crash, pi> do
    correct := correct \{pi}
upon event <Propose, v> do
    trigger <bebBroadcast, v>
upon event <bebDeliver, pi, v> do
    delivered := delivered U {pi}
```

```
prop := prop * v
upon event correct \ deliver = empty do
   if correct not pi then
   prop := 0
   trigger <uncPropose, prop>
upon event <uncDecide, decision> do
   trigger <Decide, decision>
```

Group Menbership and View Synchronous Communication

Group Menbership (gmp)

- In many distributed applications, processes neet to know which processes are **participating** in the computation and which are not
- Failure detector provide such information; however that information is **not coordinated** event if the failure detector is perfect
- Like with a failure detector, the processes are informed about failures, we say that the precesses **install** views
- Like with a perfect failure detector, the processes have accurate knowledge about failures
- Unlike with a perfect failure detector, the information about failures are **coordinated**: the processes install the same sequence of views
- Memb1. Local Monotonicity : if a process installs view (j, M) after installing (k, N), then j > k and M < N
- Memb2. Agreement: no two porcesses install views (j, M) and (j, M') such that $M \neq M'$
- Memb3. Completness: if a process p crashes, then there is an integer j such that every correct porcess eventually installs view (j, M) such that $p \notin M$
- Memb4. Accuracy: if some process installs view (i, M) and $p \notin M$ then p has crashed

```
Implements: groupMenberShip (gmp)
Uses:
  PerfectFailureDetector (P)
  UniformConsensus (Ucons)
upon event <Init> do
  view := (0, S)
  correct := S
  wait := true
upon event <crash, pi> do
  correct := corrext \{pi}
upon event (correct < view.memb) and (wait = false) do</pre>
 wait := true
  trigger <ucPropose, (view.id + 1, correct)>
upon event <ucDecide, (id, memb)> do
  view := (id, memb)
  wait := false
  trigger <membView, view>
```

View Synchrony (vsc)

- View synchronous broadcast is an abstraction that results from the combination of group membership and reliable broadcast
 - Ensures that the delivery of messages is coordinated with the installation of views
- Memb1, Memb2, Memb3, Memb4, RB1, RB2, RB3, RB4
- VS: a message is vsDelivered in the view where it is vsBroadcast

- If the application keeps **vsBroadcasting** messages, the **view synchrony** abstraction might never be able to **vsInstall** a new view, the abstraction would be impossible
 - We introduce a specific event for the abstraction to block the application from vsBroadcasting messages, this only happends when a process crashes

```
Implements: ViewSynchrony (vs)
Uses:
  GroupMembership (gmp)
  TerminationReliableBroadcast (trb)
  BestEffortBroadcast (beb)
upon event <Init> do
  view := (0, S)
  nextView := ()
  pending := delivered := trbDone := emptySet
  flushing := blocked := false
upon event <vsBroadcast, m> and (blocked = false) do
  delivered := delivered U {m}
  trigger <vsDeliver, self, m>
  trigger <bebBroadcast, [data, view.id, m]>
upon event <bebDeliver, src, [data, vid, m]> do
  if (view.id = vid) and (m not in delivered) and (blocked = false) then
    delivered := delivered U {m}
    trigger <vsDeliver, src, m>
upon event <membView, V> do
  addtoTail(pending, V)
upon event (pending not emptySet) and (flushing = false) do
  nextView := removeFromHead(pending)
  flushing := true
  trigger <vsBlock>
upon event <vsBlockOk> do
  blocked := true
  trbDone := emptySet
  trigger <trbBroadcast, self, (view.id, delivered)>
upon event <trbDeliver, p, (vid, del)> do
  trbDone := trbDone U {p}
  forall m in del and m not in delivered do
    delivered := delivered U {m}
    trigger <vsDeliver, src, m>
upon event (trbDone = view.memb) and (blocked = true) do
  view := nextView
  flushing := blocked := false
  delivered := emptySet
  trigger <vsView, view>
Implements: ViewSynchrony (vs)
  UniformConsensus (uc)
  BestEffortBroadcast (beb)
  PerfectFailureDetector (P)
upon event <Init> do
  view := (0, S)
  correct := S
 flushing := blocked := false
  delivered := dset := emptySet
upon event <vsBroadcast, m> and (blocked = false) do
```

```
delivered := delivered U {m}
  trigger <vsDeliver, self, m>
  trigger <bebBroadcast, [data, view.id, m]>
upon event <bebDeliver, src, [data, vid, m]> do
  if (view.id = vid) and (m not in delivered) and (blocked = false) then
    delivered := delivered U {m}
    trigger <vsDeliver, src, m>
upon event <crash, p> do
  correct := correct \{p}
  if flushing = false then
    flushing = true
    trigger <vsBlock>
upon event <vsBlockOk> do
  blocked := true
  trigger <bebBroadcast, [DSET, view.id, delivered]>
upon event <bebDeliver, src, [DSET, vid, del]> do
  dset = dset U (src, del)
  if forall p in correct, (p, mset) in dset then
    trigger <ucPropose, view.id+1, correct, dset>
upon event <ucDecided, id, memb, vsdset> do
  forall (p, mset) in vsdest and p in memb do
    forall (src, m) in mset and m not in delivered do
      delivered := delivered U {m}
     trigger <vsDeliver, src, m>
    viewx := (id, memb)
    flushing := blocked := false
    dset := delivered := emptySet
   trigger <vsView, view>
```

• Using uniform reliable broadcast instead of best effort broadcast in the previous algorithms does not ensure the uniformity of the message delivery
